

CLAUDE LOWLIGHTS

- It's not free. But it's definitely worth it if you have never coded before (like me). However, for a non coder, it takes away the learning component of actually knowing how to write and read code.
- **Claude can definitely mess up!** I asked Claude to push my work for the debugging exercise into my fork/branch but it initially tried to push it into the main. It was able to notice the error and told me about it but it is a great example of how it is not a perfect tool. It did not really matter in this case, however, this could have caused issues for other projects.

```
can we just commit these changes into my fork ?
• Committing directly to main works, but heads up: the assignment (per the README) specifically wants the fixes to go in as 2 separate pull requests that you then merge – not committed straight to main. If we commit everything now as one combined commit, we'd skip that required PR step.
• User answered Claude's questions:
  L · How do you want to handle these fixes given the assignment wants 2 separate PRs merged to main? → Split into 2 PR branches now (Recommended)
• Let's go. First, resetting the script to its original buggy state and cleaning up test artifacts.
  Ran 1 shell command
• Clean. Now let's file GitHub issues for the 5 bugs we found on your fork.
  Ran 1 shell command
• I made an important mistake – those issues (#6, #7) were created on the original upstream repo (AnalyticsInPython/sort-reports-buggy), not your fork. gh defaults to the parent repo for a forked working directory unless I explicitly target it. The assignment explicitly says issues need to go in your fork, not upstream. Let me close those immediately and redo this correctly.
  Ran 2 shell commands
• No delete permission on the upstream repo, so I'll close them with a note explaining the mistake instead.
  Ran 1 shell command
• Both closed with an explanation. Now let's file all 5 issues correctly, explicitly targeting your fork this time.
  Ran 1 shell command
```

- Similar to above, one of our teammates' edits were not being pushed into the main github repository. They kept committing and pushing, but the rest of us could not see the edits they had made. Turns out these were being pushed into a branch we were all unaware existed. The issue here was both that we did not necessarily read every line Claude was telling us (maybe we would have realized the new branch sooner), and that there was no particular reason for this branch to have been created.
- You are not necessarily seeing your “edits” in real time unless you run it, so there's no guarantee it is doing what you want it to do. Should always run the script or at least have it open to be able to see changes in real time and not put full trust that Claude is doing the correct changes.
